# 电子科技大学实验 报 告

学生姓名: 陶浩轩 学号: 2023080902011 指导教师: 陈端兵

#### 1. 实验室名称:

学知三组团 110139

#### 二、实验项目名称:

重要节点组挖掘

#### 三、实验原理:

本实验基于复杂网络理论,利用网络中节点的度以及节点之间的连接关系,寻找对信息传播影响最大的节点组。主要原理如下:

- 网络模型构建:将用户之间的关系抽象为网络,每个用户作为一个节点,用户之间的联系作为边。
- 节点重要性评估:
  - 度排序: 节点的度越大,其连接的节点越多,对信息传播的影响力也越大。
  - 基于投票策略: 节点根据其邻居节点的投票能力进行排序,投票能力高的节点更有可能被选中作为种子节点,从而启动信息传播。本实验中,投票能力采用 PageRank 算法计算,PageRank 算法通过分析节点之间的链接关系,评估节点在网络中的重要性。
- •信息传播模型: 采用 SIR 模型模拟信息在网络中的传播过程,评估不同节点组作为种子节点时的信息传播效果。

#### 四、实验目的:

探索在有限资源下,如何选择一组节点进行营销推广,以达到最佳效果。

- 比较度排序策略和基于投票策略在节点组选择上的优劣。
- 分析不同初始种子节点数量和感染率对信息传播效果的影响。

#### 五、实验内容:

- 1. 网络构建:利用邻接表构建用户关系网络。
- 2. 节点重要性排序:
  - 实现度排序算法。
  - 实现基于投票策略的节点排序算法,包括投票能力的计算和更新机制。
- 3. 信息传播模拟:
  - 基于 SIR 模型,模拟信息在网络中的传播过程。
  - 记录不同种子节点组合下的感染规模,作为评价标准。
- 4. 结果对比与分析:
  - 对比度排序策略和基于投票策略在感染规模上的差异。
  - 分析不同初始种子节点数量和感染率对信息传播效果的影响。

#### 六、实验器材(设备、元器件):

IDE: IntelliJ IDEA 2024.1

Java: 17.0.11 2024-04-16 LTS

OS: Windows 10

#### 七、实验步骤:

- 1. 根据选择的数据集构建 GraphReader 类,使用 Scanner 读取文件,支持读取节点与边的数量,通过邻接表构建图
- 2. 构建 PageRank 类,在初始化过程中读取节点数 N,以 int[]数组存储各个节点的 ID 与出度(故而一个节点还有一个属性: idx 下标,用于检索其 ID 与出度),用 HashMap 构建两张邻接表:二者的键都是节点的 ID,其中,graphOut 的值为一个 List<Integer>,存储其指向的节点的 ID;graphIn 的值为一个 int[],存储指向此节点的节点的 idx 下标,这是为了方便在计算 PR 时快速获得投票节点。对于出度为 0 的节点,则令其指向其他所有节点,以分摊其 PR 值,防止"吞噬" PR

3. 采用下面的公式循环计算各个节点的 PR (默认循环 500 次), 设置 d = 0.85

$$PR(A) = rac{1-d}{N} + d\left(rac{PR(B)}{L(B)} + rac{PR(C)}{L(C)} + rac{PR(D)}{L(D)} + \cdots
ight).$$

- 4. 建立记录 PageRankResult 以存储,处理 PageRank 的结果
- 5. 建立 SIRModel 类,构造函数的参数为 Map<Integer, int[]> graph,但与前面的 graphIn 不同的是,int[]存储的是 ID 而不是 idx,在 SIRModel 里面没有下标的概念。在这里,我将每个节点抽象为一个 Person,每个 Person 都有其 id 和 status。Status 是一个 enum,有 Susceptible,Infected,Recovered 三种状态。在开始模拟时,所有人的状态都是 Susceptible,我们需要传入一个含有初始感染者 id 的数组(如果没有,则随机选择),将 这些人的状态设置为 Infected。然后开始循环:遍历当前的所有已感染者,感染其邻居, 邻居按照感染概率将其状态调整至 Infected; 当遍历完后,这些感染者按照概率将状态按 照恢复率(在此实验中必然恢复)调整至 Recovered,随后不再参与模型。接着开始下一轮的感染,直到没有感染者为止或者经过了指定的感染轮数为止。最终统计所有曾经被感染的人,与总人数之比为感染率。

6. 在 Main 里面批量读取数据集,用 Page Rank,按度选择,随机选择三种策略选择重要节点,并将结果代入 SIR 模型进行测试,打印测试结果

#### 八、实验数据及结果分析:

我收集了以下数据:

• https://snap.stanford.edu/data/ca-GrQc.html

在这个简易的 SIR 模型上,以感染率 0.25, 0.5, 0.75,恢复率 1,初始感染人数为 19,最大感染轮数为 4 模拟时:

Test test\CA-GrQc.txt

Test Page Rank, the infection ratio is: 0.281572

Test Largest Degree, the infection ratio is: 0.151850

Test Randomly Select, the infection ratio is: 0.066387

-----

Test test\CA-GrQc.txt

Test Page Rank, the infection ratio is: 0.494277

Test Largest Degree, the infection ratio is: 0.295116

Test Randomly Select, the infection ratio is: 0.113506

\_\_\_\_\_

Test test\CA-GrQc.txt

Test Page Rank, the infection ratio is: 0.590424

Test Largest Degree, the infection ratio is: 0.359977

Test Randomly Select, the infection ratio is: 0.258489

\_\_\_\_\_\_

可以看到,基于投票的 page rank 算法选择出的节点较按度选择的方法相比,其传播更有效率;随着感染率的增大,感染范围扩大,但是 page rank 的优势不变

#### 九、实验结论:

在本次针对复杂网络中重要节点组挖掘的实验研究中,我们采用了度排序策略、基于投票策略的 PageRank 算法以及随机选择策略来选取种子节点,并通过 SIR 模型模拟信息传播过程,我得出了如下结论:

- 1. PageRank 算法作为一种网页排序算法,在挖掘重要节点组方面也有良好的应用。比起单一的按度选择重要节点,这种方法基于投票进行排序,能够更好地刻画节点的影响力
- 按度选择的方法具有一定的局限性,因为它并没有考虑其邻居的影响力。若是邻居的传播能力弱,就算度数高也不代表有更好的传播能力

#### 十、总结及心得体会:

PageRank 算法通过链接关系评估网页重要性,其创新性和简洁性对搜索引擎产生了深远影响,尽管存在局限性,但其迭代计算方式和广泛的应用领域证明了其强大的适用性和历史地位。

#### 十一、对本实验过程及方法、手段的改进建议:

- 1. 可以使用 ND1ib 提供的 SIR 模拟,使用 Network X 网络格式导入关系图,利用 MConfig 设置模型初始参数,以提供可视化模拟
- 2. SIR 模型传播结果的差异性与图的结构有一定关联:对于网络密度高的网络,以及较为均匀的网络,有可能两种策略的模拟结果甚至与随机选择的结果相差不大。再最开始选择数据时应当考虑这一点。
- 3. 可以尝试将挖掘出来的重要节点剔除,然后随机选择初始感染者,再进行 SIR 模型 地模拟。亦可以为原本的 SIR 模型加入更多的抽象:比如有限的医院,口罩
- 4. 亦可以使用已知关键节点的网络,将挖掘结果与之比对

报告评分:

指导教师签字:

# PageRank.java
